CALIFORNIA ENERGY FLOW IN 1982

C. K. Briggs
I. Y. Borg

October 26, 1983
Abstract

For the second year California's energy picture reflected the nationwide recession and conservation movement. Total use was down to 6.0 quads from 6.4 quads in 1980 and 6.3 quads in 1981. Preliminary data suggest that California usage fell slightly more than that of the U.S. as a whole on a percentage basis. The largest change in primary supply was in crude oil. Oil imports from foreign and out-of-state sources declined 32% and 17% respectively. Despite take-or-pay contracts with oil suppliers, utilities were successful in lowering oil used for power generation by 66%. Abundant hydropower from a wet 1981-2 winter augmented electrical supplies. Natural gas use in the state fell slightly. Power from nuclear sources remained well below historical highs due to continuing problems with the state's two licensed reactors. Purchases from small power producers by utilities (cogeneration, solid waste, wind, solar and small scale hydro) continued. Approximately 10% of new capacity in the next decade is anticipated to come from these sources. The largest cogeneration units to come on line in 1982 were in the 40-60 MW_e range. Geothermal development reached 1GW_e installed capacity.
Introduction

For the past seven years, energy flow diagrams for the State of California have been prepared from available data.\(^{1-7}\) They have proven to be useful tools in graphically expressing energy supply and use in the State as well as illustrating the large differences in energy use between California and the nation as a whole.

As far as possible similar data sources have been used to prepare the diagrams from year to year, and identical assumptions\(^ {2}\) concerning conversion efficiencies have been made in order to minimize inconsistencies in the data and analysis. In 1981, a major source of data for earlier energy flow charts was discontinued - the Quarterly Fuel and Energy Summary (QF&E), California Energy Commission (CEC). Much of the information formerly collected in QF&E is no longer published. Thus, alternate data sources, such as Department of Energy and the American Gas Association have been used in the present 1982 analysis. We continue to see differences in the data reported by various agencies for the year, thus comparisons of 1982 supply and usage based on new sources with previous years analyses based chiefly on CEC data must be done with reservations. Specifically, different aggregation into industrial/commercial/residential categories apparently has occurred which bars meaningful comparisons. Nonetheless, taken overall some generalizations can be made concerning changes in the energy picture in California. Presumably in subsequent years, closer quantitative analysis and comparison from year to year will again be possible.
DATA SOURCES

Appendices A and B summarize the primary sources used in preparation of this report. California Energy Commission publication Quarterly Oil Report provided data on gasoline, aviation and jet fuel consumption. Draft of CEC's Annual Petroleum Review 1982 was the source for data on crude oil and product imports and product exports. DOE/EIA publication Petroleum Supply Annual 1982 provided some transportation data.

As in past years the Annual Report of the State Oil and Gas Supervisor was the source for crude oil and natural gas production.

Data for electric generation are from the Electric Power Annual 1982 published by DOE/EIA. Data on electrical power imports were obtained from the Quarterly Supplement to CEC's monthly Energy Watch. Out-of-state hydro-electric power is from the Pacific Northwest (Bonneville Power Administration) and the Southwest (principally Hoover and Davis Dams on the Colorado River). The transmitted electrical power from imported hydro sources was derived from the net exchange in interstate transfers; power from out-of-state coal-fired plants is recorded separately by the CEC. Out-of-state coal fired plants are at Four Corners, Farmington, New Mexico; the Navaho Plant at Page, Arizona; and the Mohave Plant, Nevada. Data on electric sales were provided by the California Energy Commission staff.

1980 ENERGY FLOW COMPARED TO PREVIOUS YEARS

Figure 1 is the flow diagram for 1982 and Figure 2 is for the previous year. Data from other years are compiled in Table 1 for comparison.

Noteworthy changes in the supply in 1982 include:

- Drop (32%) in imported foreign oil for the second year
- Another record year for indigenous California oil production
- Large increase in California hydropower as well as imported power principally from the Pacific Northwest

N.V. Not valid (see text)
Continued decline in use of oil for electric power production - down 85% since 1978

As previously described in Data Sources, due to use of new sources comparison of energy consumption in the various end-use sectors is not valid in all instances. The problem centers on the distinction between industrial and commercial use.

The use in the "non-energy" section remains well below historical highs. This category includes petrochemicals, asphalt, waxes, fertilizer etc.; these uses produce neither heat nor mechanical work. The 1981-1982 decline in non-energy use reflects on the contraction of the fertilizer industry in the state in part due to the increased cost of natural gas under the Natural Gas Policy Act of 1978.

The net decrease in the use of total energy in 1982, 6.3 quads in 1981 compared to 6.0 quads in 1982, is related to the continuing recession. Unemployment in the state involved more than a million people or some 11% of the work force by December (Figure 3). The prime rate dropped from about 16 to 11 1/2% during the year.

For the second year the decrease in energy use had its clearest expression in the decline in the use of crude oil. Foreign imports fell substantially, and even purchase of out-of-state oil fell. In contrast to 1981, use of natural gas also fell. It was displaced by hydropower in the electrical sector. Combined conservation and mild weather (Table 2) in the southern part of the state contributed further to its decreased use. Canadian gas delivered at the border for $5.06 per thousand cubic feet comprised 14% of the total supply. Other domestic supplies cost about $3.20. Both sources are considerably cheaper than fuel oil, but because of long term contracts with take-or-pay clauses, utilities were not in all instances able to back out liquid fuel purchases for electric generation.

California oil production set an all time high of 401 million barrels.\(^{(7)}\) Increases were largely related to increased production in offshore fields (Hondo and Beta), enhanced heavy oil production and the continued high production from Elk Hills (Naval Petroleum Reserve No. 1). The latter field produced 60 million barrels, some 15% of California's total oil production, but decline had set in at the end of 1981. Comparable records were not set in indigenous natural gas production, and production decreased slightly from 1981 levels.

Use of fuels for transportation dropped significantly (Table 3) including bunkering fuels. Gasoline use appears to have remained at 1980 levels, nonetheless, substantially below 1978-9 levels. The effect of fuel conserving smaller cars in the state's fleet is not easy to discern since population increases estimated at 500,000 and the effects of the recession are also reflected in the data.

At the instigation of the California Energy Commission the State moved ahead with plans to operate a fleet of methanol-fueled cars. 506 Ford Escorts are on order and 32 fueling stations are to be built.

Natural gas again was the largest single source of electrical power in 1982. Next in importance was California and out-of-state hydro power which reflected on the heavy rainfall on the Pacific coast during the 1981-2 winter. Nuclear power remained substantially below 1979 levels due to equipment failure at the two licensed plants in the state (Rancho Seco near Sacramento and San Onofre 1 in southern California). San Onofre Unit 2 (1100 MW\(_e\)) was loaded and granted a low power license in the Spring. Malfunctions and allegations that substandard welds had been used at San Onofre resulted in a one month investigation by the Nuclear Regulatory Commission and failure to reach full power in 1982. Unit 2 is shared by four utilities (Southern California Edison, San Diego Gas and Electricity, City of Anaheim and City of Riverside). Unit 3, also 1100 MW\(_e\), is scheduled to reach criticality in 1983.

Diablo Canyon nuclear power plant that was stopped short of fuel loading in 1981 by disclosure of engineering design and construction errors was still not fuel loaded by year end. The Humboldt Bay-3 nuclear plant (63 MWₑ), out of operation for seven years, probably will be decommissioned since seismic modifications are believed to be too expensive to allow a return on the investment.

California utilities continue to be committed to buy power from sources fueled by renewable resources. Perhaps 10% of Pacific Gas & Electric Company new generating capacity will come from that source during the next decade. By 1982 the company had signed contracts to purchase 885 MWₑ from 35 cogeneration and solid waste facilities (409 MWₑ), three wind farms (382 MWₑ), nine small hydro-plants (81 MWₑ) and 48 windmills. In 1982 about 169 MWₑ new cogeneration facilities came on line, the largest of which were Kerr-McGee Chemical Company (65 MWₑ) and Crown-Zellerbach (46 MWₑ). The state's total nameplate electrical capacity was on the order of 39 MWₑ in 1982.

By the end of 1982 the largest solar power plant in the world was in operation by Southern California Edison Company and Los Angeles Water and Power on a 130 acre site southeast of Barstow. The 10 MWₑ unit consists of 1818 mirrors concentrically arranged around and focused on a boiler atop a 255 foot tower. The Department of Energy underwrote most of the cost of the $141 million test facility.

More geothermal capacity (110 MWₑ) went on line at Pacific Gas and Electric Company's Geysers steam power plant to bring the total to 1018 MWₑ. By 1988 the capacity is expected to be over 1500 MWₑ. (19)
Comparison with U.S. Energy Use

We present the 1982 U.S. Energy Flow diagram in Figure 4 because of the marked contrast between it and that for the State of California (Figure 1). Some of the historical reasons for the differences were previously summarized (7), viz. the presence of a large petroleum industry in the state, environmental constraints on fuels for electric power production, make-up of economic structure of the state and evolution of a large road system for motor vehicles. Transportation alone accounts for 37% of all energy use in California. Coal has little use in the state except as coke in the steel industry. In 1982 the recession as well as price-driven conservation affected energy use in the U.S. as well as California. Preliminary data suggest that the combined effect was slightly greater in California (down 5.4%) than in the U.S. as a whole (4.4%).
